CHAPTER

ONE

DROP IN REPLACEMENT FOR DICT

CHAPTER

TWO

SPECIFYING THE CONTAINED TYPE

If you want the nested dictionary to hold

- a collection (like the set in the first example) or
- a scalar with useful default values such as int or str.

2.1 dict of lists

```
# nested dict of lists
nd = nested_dict(2, list)
nd["mouse"]["2"].append(12)
nd["human"]["1"].append(12)
```

2.2 dict of sets

```
# nested dict of sets
nd = nested_dict(2, set)
nd["mouse"]["2"].add("a")
nd["human"]["1"].add("b")
```

2.3 dict of ints

```
# nested_dict of ints
nd = nested_dict(2, int)
nd["mouse"]["2"] += 4
nd["human"]["1"] += 5
nd["human"]["1"] += 6

nd.to_dict()
#{'human': {'1': 11}, 'mouse': {'2': 4}}
```

2.4 dict of strs

```
# nested_dict of strings
nd = nested_dict(2, str)
nd["mouse"]["2"] += "a" * 4
nd["human"]["1"] += "b" * 5
nd["human"]["1"] += "c" * 6

nd.to_dict()
#{'human': {'1': 'bbbbbccccc'}, 'mouse': {'2': 'aaaa'}}
```

ITERATING THROUGH NESTED_DICT

Iterating through deep or unevenly nested dictionaries is a bit of a pain without recursion. nested dict allows you to **flatten** the nested levels into tuples before iteration.

You do not need to know beforehand how many levels of nesting you have:

nested_dict provides

- items_flat()
- *keys_flat()*
- values_flat()

(iteritems_flat(), iterkeys_flat(), and itervalues_flat() are python 2.7-style synonyms.)

CONVERTING TO / FROM DICTIONARIES

The magic of nested_dict sometimes gets in the way (of pickleing for example).

We can convert to and from a vanilla python dict using

- nested_dict.to_dict()
- nested_dict constructor

CHAPTER

FIVE

DEFAULTDICT

nested_dict extends collections.defaultdict

You can get arbitrarily-nested "auto-vivifying" dictionaries using defaultdict.

```
from collections import defaultdict
nested_dict = lambda: defaultdict(nested_dict)
nd = nested_dict()
nd[1][2]["three"][4] = 5
nd["one"]["two"]["three"][4] = 5
```

However, only nested_dict supports a dict of dict of sets etc.

5.1 nested_dict

5.1.1 Class documentation

```
class nested_dict.nested_dict
nested_dict.__init___([existing_dict | nested_level, value_type])
```

Parameters

- existing_dict an existing dict to be converted into a nested_dict
- nested_level the level of nestedness in the dictionary
- collection_type the type of the values held in the dictionary

For example,

```
a = nested_dict(3, list)
a['level 1']['level 2']['level 3'].append(1)

b = nested_dict(2, int)
b['level 1']['level 2']+=3
```

If nested_level and value_type are not defined, the degree of nested-ness is not fixed. For example,

```
a = nested_dict()
a['1']['2']['3'] = 3
a['A']['B'] = 15
```

```
nested_dict.iteritems_flat()
    python 2.7 style synonym for items_flat()
```

```
nested_dict.items_flat()
```

iterate through values with nested keys flattened into a tuple

For example,

```
from nested_dict import nested_dict
a = nested_dict()
a['1']['2']['3'] = 3
a['A']['B'] = 15
```

print list(a.items_flat())

Produces:

```
[ (('1', '2', '3'), 3), (('A', 'B'), 15)]
```

```
nested_dict.iterkeys_flat()
```

python 2.7 style synonym for keys_flat ()

```
nested_dict.keys_flat()
```

iterate through values with nested keys flattened into a tuple

For example,

```
from nested_dict import nested_dict
a = nested_dict()
a['1']['2']['3'] = 3
a['A']['B'] = 15

print list(a.keys_flat())
```

Produces:

```
[('1', '2', '3'), ('A', 'B')]
```

```
nested_dict.itervalues_flat()
```

python 2.7 style synonym for values_flat()

```
nested_dict.values_flat()
```

iterate through values as a single list, without considering the degree of nesting

For example,

```
from nested_dict import nested_dict
a = nested_dict()
a['1']['2']['3'] = 3
a['A']['B'] = 15

print list(a.values_flat())
```

Produces:

```
[3, 15]
```

```
nested_dict.to_dict()
```

Converts the nested dictionary to a nested series of standard dict objects

For example,

```
from nested_dict import nested_dict
a = nested_dict()
a['1']['2']['3'] = 3
a['A']['B'] = 15

print a.to_dict()
```

Produces:

```
{'1': {'2': {'3': 3}}, 'A': {'B': 15}}
```

```
nested_dict.__str__([indent])
```

The dictionary formatted as a string

Parameters indent - The level of indentation for each nested level

For example,

```
from nested_dict import nested_dict
a = nested_dict()
a['1']['2']['3'] = 3
a['A']['B'] = 15

print a
print a.__str__(4)
```

Produces:
